Name: ID#: Lab Time:

CS 4061: Practice Exam 1

Spring 2019 University of Minnesota

Exam period: 30 minutes Points available: 40

Problem 1 (10 pts): Examine the code to the right and describe what you expect its output to be. Explain why or why not you would expect to see any specific ordering in the output of the program.

Problem 2 (10 pts): Write the function total_doubles() described and demonstrated below.

```
1 #include <stdio.h>
2 int total_doubs(char *fname,
                                      // file to read
                   double *total);
                                      // set to total
4 // Read doubles from the named file which contains
_{5} // binary doubles. Sum all the numbers in the file
_{6} // and set the double pointed to by total to this
7 // value. Return the count of numbers or -1 if
8 // the file could not be opened.
9
10 int main(){
11
    char *fname = "nums.dat";
12
    int n_{doubs} = -1;
    double total = -1;
13
    n_doubs = total_doubs("nums.dat", &total);
14
    printf("%d nums read totaling %lf\n",
15
           n_doubs, total);
16
    return 0;
17
18 }
```

Problem 3 (5 pts): Stan Dardin is interactively testing his implementation of commando by punching in commands like list, output-for 2, gcc test.c by hand. He is finding that he keeps making mistakes while entering commands causing him to have to restart the program. He is not ready to run the full tests provided by Prof. Coffmalevolent, just the few things he knows works but the tedium is making it hard to proceed. Suggest an easy way for Stan to enter his commands more easily using tools and syntax provided in every Unix shell.

Background: If a commando user mistypes the name of a program like fcc rather than gcc strange output might occur. The next problems address this by making changes to commando so that it behaves like the example to the right.

Problem 4 (15 pts): Standard output for commando programs is directed into a pipe but standard error is not. Add code to cmd_start() in the template given which directs standard error into the output pipe associated with the cmd_t.

Add code to the template for cmd_update_state() that checks for special exit codes that signify exec problems and sets fields of the cmd_t appropriately. Some code for this problem may be identical to what is already in your project.

```
#define EXEC_FAIL 128
                                                       #define FORK_ERROR 128
void cmd_start(cmd_t *cmd){
                                                       void cmd_update_state(cmd_t *cmd, int block){
  ... // VARIOUS SETUP
                                                         ... // VARIOUS SETUP
 cmd->pid = fork();
                                                         pid_t ret = waitpid(cmd->pid, &status, block);
                                                         // CHECK IF status INDICATES CHILD HAS EXITED
  if(cmd->pid != 0){...} // PARENT
  else{
                          // CHILD
                                                         // SET DATA ASSOCIATED WITH IT APPROPRIATELY
                                                         // CHECK FOR SPECIAL RETURN VALUE FORK_ERROR
    // normal standard output redirection set up
                                                         // AND SET THE str_status FIELD TO "EXEC FAIL"
    // YOUR CODE FOR STDERR REDIRECTION HERE
                                                         // OTHERWISE SET DATA AS NORMAL IN PROJECT
                                                         if(
                                                                                              ){
   // FINISHED WITH STDERR REDIRECTION
   // Call to execvp(), on error, call perror()
   // and exit with code EXEC_FAIL.
   // YOUR CODE FOR EXEC/RETURN HERE
                                                         } // FINISHED CHECKING ON EXIT
                                                         ... // PRINT ALERTS
```

(Note: In a normal exam, more space will be provided for answers.)
